

Ouroboros V2s testing breakthrough roadblocks

* Over the past several days we have been trying to achieve self sustained powering with ... mixed results.

* Best case scenario was SCALAR compression of the ~~B~~ vector intersection resulting in $\approx 100\%$ energy back into the coils. After removing half of the "MEG" I am concluding what we have been seeing is typical inductance. Below is the best case scenario circuit & we did have a 200% efficient oscilloscope capture of it working at one point (01/29/2024) but since then; I have been un-able to re-produce similar results...

* From this model ~ it seemed to have ~~200%~~ efficiency i.e. over-unity. But! we cannot get it replicated despite my best efforts.
